Wipes can physically work microorganisms, and by leaving chemicals on the skin to kill or disable remaining microorganisms. Gels and rubs rely on killing or disabling the microorganisms in situ, so they cannot cause infection. Some microorganisms may be resistant to chemicals and antiseptics. Clostridium difficile and norovirus are resistant to alcohol, while Pseudomonas aeruginosa thrives in chlorhexidine; therefore these products may be of little use when trying to control infections caused by these organisms. Practitioners should be wary of products that claim to kill 99.9% of bacteria eÁÁÁ they are unlikely to kill spores, fungi and viruses. Are all HCÁIs unavoidable? About 30% of these infections will occur despite best efforts to prevent them. Resident microorganisms cause no harm if they remain on or in their normal resident area, but if relocated they can cause infection. Escherichia coli is necessary for a healthy gut but if transferred to the sterile urinary tract causes infection. Endogenous infections are caused by patientseÁÁÁ own resident microorganisms. Surgical or invasive device infections are often endogenous. High standards of patient hygiene can reduce, but not eliminate, the risk of endogenous infection. Which patients are most vulnerable to HCAÍ? Patients on chemotherapy or steroids are often immunocompromised and vulnerable to infection. The very young and the elderly may not mount an effective immune response to infection; cases of MRSA and C. difficile are more common in patients over 65.Each day spent in healthcare settings increases patientseÁÁÁ risk of acquiring an HCAI. The high burden of microorganisms, inappropriate use of antibiotics and healthcare interventions which breach or bypass vital parts of the immune system, all increase risk. When considering average hospital or care home populations those most at risk are elderly long-stay patients, who are taking or recently had antibiotics, and who have invasive or break on the skin.
